# **Recurrent Neural Networks**

#### CALIFICACIÓN DEL ÚLTIMO ENVÍO

## 100%

1. Suppose your training examples are sentences (sequences of words). Which of the following refers to the  $j^{th}$  word in the  $i^{th}$  training example?

1 / 1 puntos

$$x^{< i > (j)}$$

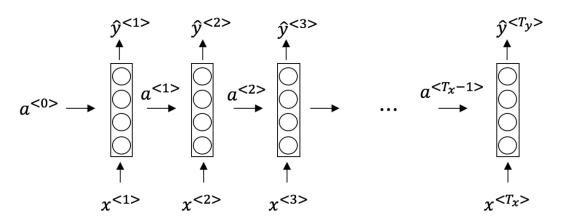

$$(x^{(j)< i>})$$

$$\int x^{< j>(i)}$$

#### ✓ Correcto

We index into the  $i^{th}$  row first to get the  $i^{th}$  training example (represented by parentheses), then the  $j^{th}$  column to get the  $j^{th}$  word (represented by the brackets).

2. Consider this RNN: 1/1 puntos

This specific type of architecture is appropriate when:

$$T_x = T_y$$

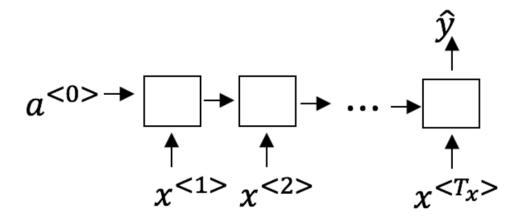

$$T_x < T_y$$

$$T_x > T_y$$

- $T_x = 1$ 
  - ✓ Correcto

It is appropriate when every input should be matched to an output.

To which of these tasks would you apply a many-to-one RNN architecture? (Check all that 1 / 1 puntos apply).

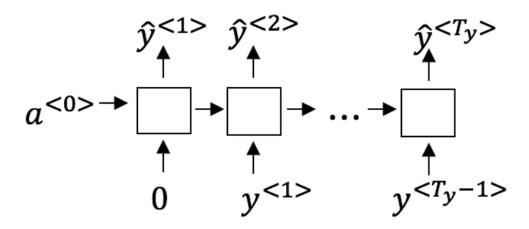

- Speech recognition (input an audio clip and output a transcript)
- Sentiment classification (input a piece of text and output a 0/1 to denote positive or negative sentiment)
  - ✓ Correcto

Correct!

- Image classification (input an image and output a label)
- Gender recognition from speech (input an audio clip and output a label indicating the speaker's gender)
  - Correcto

1 / 1 puntos

4. You are training this RNN language model.

At the  $t^{th}$  time step, what is the RNN doing? Choose the best answer.

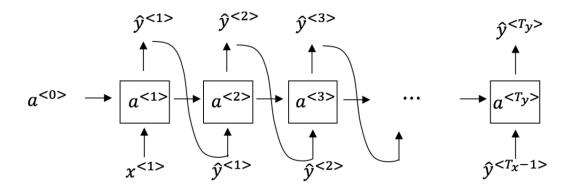

- $\bigcirc \quad \text{Estimating } P(y^{< t>})$
- **Section 2** Estimating  $P(y^{< t>} | y^{< 1>}, y^{< 2>}, \dots, y^{< t-1>})$
- Stimating  $P(y^{< t>} | y^{< 1>}, y^{< 2>}, \dots, y^{< t>})$

#### Correcto

Yes, in a language model we try to predict the next step based on the knowledge of all prior steps.

5. 1 / 1 puntos

You have finished training a language model RNN and are using it to sample random sentences, as follows:

What are you doing at each time step t?

- (i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as  $\hat{y}^{<\ell>}$ . (ii) Then pass the ground-truth word from the training set to the next time-step.
- (i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as  $\hat{y}^{<\ell>}$ . (ii) Then pass the ground-truth word from the training set to the next time-step.
- (i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as  $\mathcal{V}^{< l^{>}}$ . (ii) Then pass this selected word to the next time-step.
- (i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as  $\hat{y}^{<\ell>}$ . (ii) Then pass this selected word to the next time-step.

## ✓ Correcto

Yes!

6. You are training an RNN, and find that your weights and activations are all taking on the value of NaN ("Not a Number"). Which of these is the most likely cause of this problem?

1 / 1 puntos

- Vanishing gradient problem.
- Exploding gradient problem.
- ReLU activation function g(.) used to compute g(z), where z is too large.
- Sigmoid activation function g(.) used to compute g(z), where z is too large.

V COLLECTO

7. Suppose you are training a LSTM. You have a 10000 word vocabulary, and are using an LSTM with 100-dimensional activations  $a^{<\!\!\!\!/\!\!\!\!\!/}$ . What is the dimension of  $\Gamma_u$  at each time step?

1 / 1 puntos

- $\bigcirc$  1
- 100
- 300
- 10000
  - ✓ Correcto

 $a^{<t>} = c^{<t>}$ 

Correct,  $\Gamma_u$  is a vector of dimension equal to the number of hidden units in the LSTM.

8. Here're the update equations for the GRU.

1 / 1 puntos

#### GRU

$$\tilde{c}^{} = \tanh(W_c[\Gamma_r * c^{}, x^{}] + b_c)$$

$$\Gamma_u = \sigma(W_u[c^{}, x^{}] + b_u)$$

$$\Gamma_r = \sigma(W_r[c^{}, x^{}] + b_r)$$

$$c^{} = \Gamma_u * \tilde{c}^{} + (1 - \Gamma_u) * c^{}$$

Alice proposes to simplify the GRU by always removing the  $\Gamma_u$ . I.e., setting  $\Gamma_u$  = 1. Betty proposes to simplify the GRU by removing the  $\Gamma_r$ . I. e., setting  $\Gamma_r$  = 1 always. Which of these models is more likely to work without vanishing gradient problems even when trained on very long input sequences?

Alice's model (removing  $\Gamma_u$ ), because if  $\Gamma_r \approx 0$  for a timestep, the gradient can propagate back through that timestep without much decay.

- Alice's model (removing  $\Gamma_u$ ), because if  $\Gamma_r \approx 1$  for a timestep, the gradient can propagate back through that timestep without much decay.
- Betty's model (removing  $\Gamma_r$ ), because if  $\Gamma_u \approx 0$  for a timestep, the gradient can propagate back through that timestep without much decay.
- Betty's model (removing  $\Gamma_r$ ), because if  $\Gamma_u \approx 1$  for a timestep, the gradient can propagate back through that timestep without much decay.

Yes. For the signal to backpropagate without vanishing, we need  $c^{<\!t^>}$  to be highly dependant on  $c^{<\!t^-1^>}$ .

9. Here are the equations for the GRU and the LSTM:

1 / 1 puntos

GRU

$$\tilde{c}^{< t>} = \tanh(W_c[\Gamma_r * c^{< t-1>}, x^{< t>}] + b_c)$$

$$\Gamma_u = \sigma(W_u[\ c^{< t-1>}, x^{< t>}] + b_u)$$

$$\Gamma_r = \sigma(W_r[\,c^{< t-1>},x^{< t>}] + b_r)$$

$$c^{< t>} = \Gamma_u * \tilde{c}^{< t>} + (1 - \Gamma_u) * c^{< t - 1>}$$

$$a^{} = c^{}$$

#### LSTM

$$\tilde{c}^{< t>} = \tanh(W_c[a^{< t-1>}, x^{< t>}] + b_c)$$

$$\Gamma_u = \sigma(W_u[a^{< t-1>}, x^{< t>}] + b_u)$$

$$\Gamma_f = \sigma(W_f[a^{< t-1>}, x^{< t>}] + b_f)$$

$$\Gamma_o = \sigma(W_o[a^{< t-1>}, x^{< t>}] + b_o)$$

$$c^{< t>} = \ \Gamma_u * \tilde{c}^{< t>} + \Gamma_f * c^{< t-1>}$$

$$a^{< t>} = \Gamma_o * c^{< t>}$$

From these, we can see that the Update Gate and Forget Gate in the LSTM play a role similar to \_\_\_\_\_ and \_\_\_\_ in the GRU. What should go in the the blanks?

- $\Gamma_u$  and  $1 \Gamma_u$
- $\bigcap$   $\Gamma_u$  and  $\Gamma_r$
- $1 \Gamma_u$  and  $\Gamma_u$
- $\bigcap$   $\Gamma_r$  and  $\Gamma_u$

### Correcto

Yes, correct!

untos

10.	You have a pet dog whose mood is heavily dependent on the current and past few days'	1 / 1 pt
	weather. You've collected data for the past 365 days on the weather, which you represent	•
	as a sequence as $x^{<1>}, \dots, x^{<365>}$ . You've also collected data on your dog's mood, which	
	you represent as $y^{<1>}, \dots, y^{<365>}$ . You'd like to build a model to map from $x \to y$ .	
	Should you use a Unidirectional RNN or Bidirectional RNN for this problem?	
	Didirectional DNN because this allows the prediction of mond on down to take into	

- Bidirectional RNN, because this allows the prediction of mood on day t to take into account more information.
- Bidirectional RNN, because this allows backpropagation to compute more accurate gradients.
- O Unidirectional RNN, because the value of  $y^{< t>}$  depends only on  $x^{< 1>}, \dots, x^{< t>}$ , but not on  $x^{< t+1>}, \dots, x^{< 365>}$
- Unidirectional RNN, because the value of  $y^{<\!\!\!/\!\!\!>}$  depends only on  $x^{<\!\!\!/\!\!\!>}$ , and not other days' weather.

Correcto

Yes!
